

1. Problem Statement

Office teams, students and small organizations often need routine legal drafts but may not know the structure, wording or formatting required to prepare them efficiently. The project addresses this by converting a small set of user-supplied facts into an editable, structured legal draft.

2. Proposed Idea

LegalEase is an AI-assisted legal document drafting workspace. The user selects a document type, enters the parties, effective-date details and terms, and requests a draft. The application sends the request to a FastAPI backend, which generates the document through Google Gemini or a local demo path, then returns the result to the Streamlit interface.

3. Objectives

- Reduce the time needed to produce a first legal-document draft.
- Provide a structured and readable draft with headings, clauses and signature blocks.
- Avoid inventing missing material facts by using bracketed placeholders.
- Allow review and editing before export.
- Export the finished draft as TXT, DOCX and PDF.
- Provide a demonstrable academic project with a clear AI + web application architecture.

4. Target Users and Use Cases

User	Need	Example use case
Student / trainee	Learn and demonstrate legal drafting workflow	Create an NDA for a project demonstration
Office staff	Prepare a first draft quickly	Draft a service agreement from known terms
Small business user	Convert agreed business terms into a formatted draft	Prepare an employment or freelance contract
Reviewer / mentor	Inspect and edit generated content	Review clauses and placeholders before export

5. Scope

- In scope: structured legal draft generation, user editing, preview, TXT/DOCX/PDF export, demo mode, API validation and automated tests.
- Out of scope: legal advice, jurisdiction-specific legal verification, electronic signatures, case-law research, matter management and persistent user accounts.

6. Feasibility Snapshot

Dimension	Assessment	Reason
Technical	Feasible	Built with Python, Streamlit, FastAPI, Google GenAI, python-docx and fpdf2.
Operational	Feasible	Single workspace flow with a small number of required inputs.
Economic	Moderate	Main variable cost is access to the AI provider; demo mode can be used locally.
Academic	Strong fit	Covers AI integration, API design, UI, document export and software testing.

7. Initial Design Decisions

- Use Streamlit for the user-facing application to simplify development and demonstration.
- Use FastAPI as an internal service boundary between UI and AI generation.
- Use a model-selection and fallback strategy so generation is not tightly coupled to one configured model ID.
- Keep generated output editable and exportable rather than treating the AI response as final legal advice.

Key idea: LegalEase should make the first draft easier to produce, while preserving a human review step before the document is used.
